

Software Architecture — Data Flow

A simple model showing how a web application can turn user activity into analytics.

Application Data Flow → Database → Analytics

Logging and error handling support the backend and data pipeline.

The frontend captures user actions. The backend/API validates requests and applies business logic. The database stores application data. A data pipeline cleans and transforms records for analysis. SQL/Python or another analytics layer calculates KPIs, and the dashboard presents the results. Logging and error handling help analysts and developers trace data-quality or application problems.
